

5 purification by binding to nickel immobilized on a suitable support, epitopes for polyclonal or  
monoclonal antibodies including but not limited to the T7 epitope, the myc epitope, and the  
V5a epitope, and fusion of Hu-Asp2 to suitable protein partners including but not limited to  
10 glutathione-S-transferase or maltose binding protein. In a preferred embodiment these  
5 additional amino acid sequences are added to the C-terminus of Hu-Asp but may be added to  
the N-terminus or at intervening positions within the Hu-Asp2 polypeptide.

The present invention also relates to vectors comprising the polynucleotide molecules  
15 of the invention, as well as host cell transformed with such vectors. Any of the polynucleotide  
molecules of the invention may be joined to a vector, which generally includes a selectable  
10 marker and an origin of replication, for propagation in a host. Because the invention also  
provides Hu-Asp polypeptides expressed from the polynucleotide molecules described above,  
20 vectors for the expression of Hu-Asp are preferred. The vectors include DNA encoding any of  
the Hu-Asp polypeptides described above or below, operably linked to suitable transcriptional  
or translational regulatory sequences, such as those derived from a mammalian, microbial,  
25 viral, or insect gene. Examples of regulatory sequences include transcriptional promoters,  
operators, or enhancers, mRNA ribosomal binding sites, and appropriate sequences which  
control transcription and translation. Nucleotide sequences are operably linked when the  
regulatory sequence functionally relates to the DNA encoding Hu-Asp. Thus, a promoter  
30 nucleotide sequence is operably linked to a Hu-Asp DNA sequence if the promoter nucleotide  
20 sequence directs the transcription of the Hu-Asp sequence.

Selection of suitable vectors to be used for the cloning of polynucleotide molecules  
35 encoding Hu-Asp, or for the expression of Hu-Asp polypeptides, will of course depend upon  
the host cell in which the vector will be transformed, and, where applicable, the host cell from  
which the Hu-Asp polypeptide is to be expressed. Suitable host cells for expression of Hu-  
25 Asp polypeptides include prokaryotes, yeast, and higher eukaryotic cells, each of which is  
discussed below.

The Hu-Asp polypeptides to be expressed in such host cells may also be fusion  
proteins which include regions from heterologous proteins. Such regions may be included to  
45 allow, e.g., secretion, improved stability, or facilitated purification of the polypeptide. For  
30 example, a sequence encoding an appropriate signal peptide can be incorporated into  
expression vectors. A DNA sequence for a signal peptide (secretory leader) may be fused  
in-frame to the Hu-Asp sequence so that Hu-Asp is translated as a fusion protein comprising  
50 the signal peptide. A signal peptide that is functional in the intended host cell promotes

extracellular secretion of the Hu-Asp polypeptide. Preferably, the signal sequence will be cleaved from the Hu-Asp polypeptide upon secretion of Hu-Asp from the cell. Non-limiting examples of signal sequences that can be used in practicing the invention include the yeast I-factor and the honeybee melatin leader in sf9 insect cells.

In a preferred embodiment, the Hu-Asp polypeptide will be a fusion protein which includes a heterologous region used to facilitate purification of the polypeptide. Many of the available peptides used for such a function allow selective binding of the fusion protein to a binding partner. For example, the Hu-Asp polypeptide may be modified to comprise a peptide to form a fusion protein which specifically binds to a binding partner, or peptide tag. Non-limiting examples of such peptide tags include the 6-His tag, thioredoxin tag, hemagglutinin tag, GST tag, and OmpA signal sequence tag. As will be understood by one of skill in the art, the binding partner which recognizes and binds to the peptide may be any molecule or compound including metal ions (e.g., metal affinity columns), antibodies, or fragments thereof, and any protein or peptide which binds the peptide, such as the FLAG tag.

Suitable host cells for expression of Hu-Asp polypeptides includes prokaryotes, yeast, and higher eukaryotic cells. Suitable prokaryotic hosts to be used for the expression of Hu-Asp include bacteria of the genera *Escherichia*, *Bacillus*, and *Salmonella*, as well as members of the genera *Pseudomonas*, *Streptomyces*, and *Staphylococcus*. For expression in, e.g., *E. coli*, a Hu-Asp polypeptide may include an N-terminal methionine residue to facilitate expression of the recombinant polypeptide in a prokaryotic host. The N-terminal Met may optionally then be cleaved from the expressed Hu-Asp polypeptide. Other N-terminal amino acid residues can be added to the Hu-Asp polypeptide to facilitate expression in *Escherichia coli* including but not limited to the T7 leader sequence, the T7-caspase 8 leader sequence, as well as others leaders including tags for purification such as the 6-His tag (Example 9). Hu-Asp polypeptides expressed in *E. coli* may be shortened by removal of the cytoplasmic tail, the transmembrane domain, or the membrane proximal region. Hu-Asp polypeptides expressed in *E. coli* may be obtained in either a soluble form or as an insoluble form which may or may not be present as an inclusion body. The insoluble polypeptide may be rendered soluble by guanidine HCl, urea or other protein denaturants, then refolded into a soluble form before or after purification by dilution or dialysis into a suitable aqueous buffer. If the inactive proform of the Hu-Asp was produced using recombinant methods, it may be rendered active by cleaving off the prosegment with a second suitable protease such as human immunodeficiency virus protease.

5 Expression vectors for use in prokaryotic hosts generally comprises one or more phenotypic selectable marker genes. Such genes generally encode, e.g., a protein that confers antibiotic resistance or that supplies an auxotrophic requirement. A wide variety of such vectors are readily available from commercial sources. Examples include pSPORT vectors, 10 pGEM vectors (Promega), pPROEX vectors (LTI, Bethesda, MD), Bluescript vectors (Stratagene), pET vectors (Novagen) and pQE vectors (Qiagen).

15 Hu-Asp may also be expressed in yeast host cells from genera including *Saccharomyces*, *Pichia*, and *Kluyveromyces*. Preferred yeast hosts are *S. cerevisiae* and *P. pastoris*. Yeast vectors will often contain an origin of replication sequence from a 2T yeast plasmid, an autonomously replicating sequence (ARS), a promoter region, sequences for polyadenylation, sequences for transcription termination, and a selectable marker gene. 20 Vectors replicable in both yeast and *E. coli* (termed shuttle vectors) may also be used. In addition to the above-mentioned features of yeast vectors, a shuttle vector will also include sequences for replication and selection in *E. coli*. Direct secretion of Hu-Asp polypeptides 25 expressed in yeast hosts may be accomplished by the inclusion of nucleotide sequence encoding the yeast I-factor leader sequence at the 5' end of the Hu-Asp-encoding nucleotide sequence.

30 Insect host cell culture systems may also be used for the expression of Hu-Asp polypeptides. In a preferred embodiment, the Hu-Asp polypeptides of the invention are expressed using an insect cell expression system (see Example 10). Additionally, a baculovirus expression system can be used for expression in insect cells as reviewed by 35 Luckow and Summers, *Bio/Technology* 6:47 (1988).

40 In another preferred embodiment, the Hu-Asp polypeptide is expressed in mammalian host cells. Non-limiting examples of suitable mammalian cell lines include the COS-7 line of monkey kidney cells (Gluzman *et al.*, *Cell* 23:175 (1981)), human embryonic kidney cell line 293, and Chinese hamster ovary (CHO) cells. Preferably, Chinese hamster ovary (CHO) cells are used for expression of Hu-Asp proteins (Example 11).

45 The choice of a suitable expression vector for expression of the Hu-Asp polypeptides of the invention will of course depend upon the specific mammalian host cell to be used, and 50 is within the skill of the ordinary artisan. Examples of suitable expression vectors include pcDNA3 (Invitrogen) and pSVL (Pharmacia Biotech). A preferred vector for expression of Hu-Asp polypeptides is pcDNA3.1-Hygro (Invitrogen). Expression vectors for use in mammalian host cells may include transcriptional and translational control sequences derived
